ML Algorithm Steps

08 April 2024 16:27

① Define Business case / problem statement

② Import basic libraries
↳ numpy, pandas, seaborn

③ Load data.

④ Domain analysis.

⑤ Basic checks
↳ check shape, head, tail, info, dtype, describe

⑥ Exploratory Data analysis → understand data by plotting graphs / charts using seaborn

* Univariate analysis – analysis on single column.
→ histogram, countplot.

* Bivariate analysis → analysis on 2 variable/column.
→ Scatter plot, line plot, ...

* Multivariate analysis → analysis of more than one column.
→ pair plot.

⑦ Data preprocessing / Data cleaning.
↳ Find missing values.
↳ check outliers.
↳ convert categorical data to numerical.
↳ Balancing data.
→ scaling data.

⑧ Feature selection
↳ Dropping of unwanted columns.
↳ check correlation

⑨ Model creation
1) Independent & dependent variable creation.
X → contains all input column.
Y → contains output column
2) Training & testing data creation.

2) Training & testing data creation.

split the data for training & testing

X → train, test

y → train, test.

[X_train, X_train, X_test, y_test]

*test_size = 0.30.

3) create model

4) Model Evaluation :
